

Forward Simulation and KL-Divergence Results for All Conditions

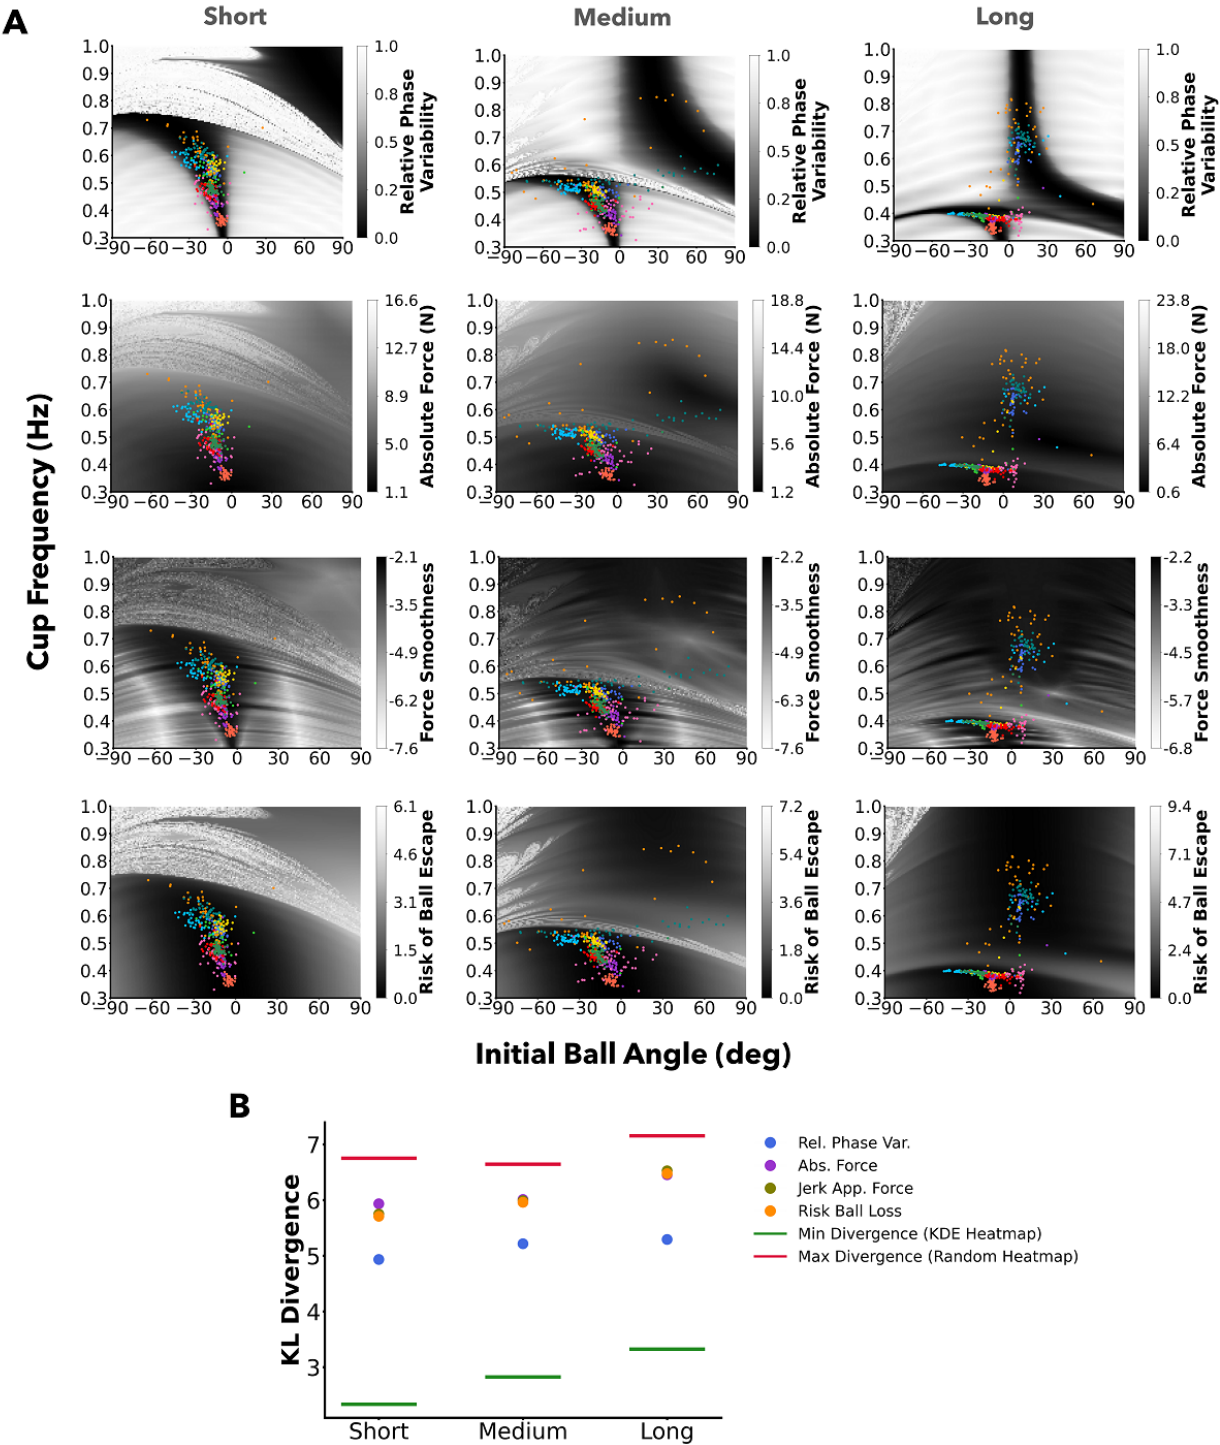

Fig A. Heatmaps for all variables and KL-divergence values for the random protocol. A) Heatmaps of the relative phase variability (row 1), absolute force (row 2), force smoothness (row 3) and risk of ball escape (row 4), for combinations of initial ball angles and cup frequencies plotted in grey shades in the background. Participant choices of initial ball angle and cup frequency from all trials are plotted as colored points in the foreground. Colors represent different participants. **B)** KL-divergence values between the

9 distribution of the participant data and the underlying heatmaps shown for the different variables and
10 pendulums in **A**.

11 A heatmap of relative phase variability, absolute applied force, log dimensionless
12 jerk of applied force, and risk of ball escape was plotted from simulation runs of all com-
13 binations of desired cup frequency and initial ball angle for each pendulum (Fig AA).
14 Participant data from all trials was superimposed on the heatmap for the Random proto-
15 col.

16 The corresponding KL-divergence values between the participant data and the un-
17 derlying heatmap are shown in (Fig AB). An estimate for minimum KL-divergence was ob-
18 tained using a Kernel Density Estimate of the participant data as the underlying heatmap.
19 An estimate for maximum KL-divergence was obtained using a random probability den-
20 sity heatmap as the underlying heatmap. The mean of KL-divergences from 100 ran-
21 domly sampled probability density heatmaps was set as the maximum KL-divergence
22 estimate.

23 **Cost Function Descriptions for the Stochastic Optimal Open-loop Simulations**

24 Considering the desired state trajectories and minimization of variance around the
25 desired states, the following cost function was adopted:

$$J = (X_f - X_f^d)^T Q_f (X_f - X_f^d) + \text{Tr}(Q_f^v P_f) + \int_0^{t_f} ((X_t - X_t^d)^T Q_t (X_t - X_t^d) + \text{Tr}(Q_t^v P_t) + u_t^T R_t u_t) dt \quad (1)$$

26 where the subscripts t and f represent trial time and the end of trial (terminal) time,
27 respectively. X and X^d are the state vector and desired state vectors respectively, P is
28 the state covariance matrix, Q is the state cost weighting matrix, Q^v is the covariance
29 cost weighting matrix. u is the control vector, R is the control cost weighting matrix, and
30 Tr is the trace of the matrix. The total simulation time was $t_f = 8 \text{ s}$ with a step size of
31 $\Delta t = 10 \text{ ms}$ resulting to a total of 800 simulation steps.

For reference, the state vector and the control vector were defined in the manuscript text as follows:

$$\begin{aligned} X_t &= [x_t, v_t, \theta_t, \omega_t, l_t, F_t, K_t, \dot{F}_t, \dot{K}_t] \\ u_t &= [\ddot{K}_t, \ddot{F}_{ff_t}] \end{aligned} \quad (2)$$

Rhythmic Stage: The desired position trajectory of the cup and velocity of the cup was designed as $x^d = A \cos(2\pi ft)$ and $v^d = -2\pi f A \sin(2\pi ft)$, respectively. Quadratic costs were enabled on K and F_{ff} and their first derivative to limit true control magnitudes. The state weighting matrices Q_f , Q_f^v , Q_t , Q_t^v and the pseudo-control cost matrix R_t for the rhythmic stage (*time step* : $t \in (200, 800]$) of the simulations were designed as below.

$$\begin{aligned} Q_{t>200} &= Q_{t=800} = 50 \text{diag}(1, 0.1, 0, 0, 1^{-12}, 1^{-12}, 1^{-6}, 1^{-6}, 0) \\ Q_{t>200}^v &= Q_{t=800}^v = 100 \text{diag}(1, 0.5, 0, 0, 0, 0, 0, 0, 0) \\ R_{t>0} &= 1^{-6} \text{diag}(1, 1) \end{aligned} \quad (3)$$

Preparation Stage: There were no desired cup or ball states during the preparation stage. Quadratic costs were enabled on K and F_{ff} and their first derivative. The state cost matrices for the preparation stage of the simulation (*time step* : $t \in [0, 200)$) were as follows:

$$\begin{aligned} Q_{t<200} &= 50 \text{diag}(0, 0, 0, 0, 1^{-12}, 1^{-12}, 1^{-6}, 1^{-6}, 0) \\ Q_{t<200}^v &= 100 \text{diag}(0, 0, 0, 0, 0, 0, 0, 0, 0) \end{aligned} \quad (4)$$

Last Preparation Step: The desired state of the ball θ was varied in the simulation, and the state of the cup was $x = -0.15 \text{ m}$ and $v = 0 \text{ m/s}$. The state cost matrices for the last step of preparation stage (*time step* : $t = 200$) of the simulation were set accordingly.

$$\begin{aligned} Q_{t=200} &= 50 \text{diag}(0, 0, 10, 1, 1^{-12}, 1^{-12}, 1^{-6}, 1^{-6}, 0) \\ Q_{t=200}^v &= 100 \text{diag}(0, 0, 10, 5, 0, 0, 0, 0, 0) \end{aligned} \quad (5)$$
